

From Subscription to Venture Intelligence
A New Economic and Production Model Proposal for AI Platforms
Concept Owner: Murat Karmil
Structural Editing: AI-assisted

Abstract

Today's AI platforms largely operate through subscription-based and usage-based economic models.

This model is powerful, scalable, and suitable for mass adoption.

However, it has a structural limitation:

The system evaluates low-impact usage and high-potential production processes within the same economic category.

One user may generate entertainment content, while another may build products, patents, startups, technical infrastructure, or systems with high economic value using the same AI platform.

The current model does not strategically or economically differentiate between these users.

This paper proposes the following:

AI platforms can evolve beyond service providers into ecosystems that discover, support, develop, and co-create value with builders.

This model is defined as:

Venture Intelligence Ecosystem (VIE)

1. The Current Problem: Equal Usage Does Not Mean Equal Value

The current system is simple:

The user arrives.

Uses the system.

Pays.

But the core limitation is this:

Not every usage generates the same economic value.

Some usages produce:

entertainment

consumption

time passing

Others produce:

products

patents

startups

technical systems

economic value

These should not be treated as the same economic category.

2. The Invisible Builder Problem

There are many high-potential builders in the world.

But most remain invisible.

Because of:

lack of hardware

lack of compute power

lack of financing

lack of mentorship

lack of testing infrastructure

lack of direction

The problem is not lack of talent.

The problem is lack of access.

Talent distribution and resource distribution are not equal.

This gap creates systematic value loss.

3. AI Already Sees the Signals

AI systems can already detect important signals through long-term interaction:

question quality

technical depth

problem-solving patterns

production consistency

system-building instinct

innovation behavior

cross-disciplinary thinking

The problem is not that AI cannot see these signals.
The problem is that these signals are not converted into an economic and production model.

4. The First Layer: AI Flag System

AI does not decide.

It only generates signals.

Example signals:

Builder Signal

Is this person a builder?

Consistency Signal

Does this person have long-term production potential?

Technical Depth Signal

Can this person carry real technical problems?

Innovation Signal

Can this person generate new solutions?

Applicability Signal

Can this idea be brought into the real world?

AI signals.

Humans decide.

5. The Second Layer: Human Evaluation

The actual decision happens here.

The team evaluates:

applicability

economic value

technical correctness

scalability

sustainability

strategic value

This layer requires humans.

Because AI points.

Humans decide.

6. The Third Layer: Live Validation

Written communication shows ideas.

Live communication shows the person.

At this stage, it becomes clear:

is this person the real owner of the idea?

can they defend it?

are they open to criticism?

can they work in a team?

is their thought process consistent?

can the idea survive pressure?

This is a character and compatibility test.
The team sees this best.

7. The Fourth Layer: Commitment and Execution Discipline
High-quality ideas alone are not enough.
Execution discipline must also be evaluated.
This includes:

time allocated to the project

production intensity

consistency

work discipline

target tracking

delivery capacity

One builder may work a few hours per week.
Another may work 12-18 hours per day at the same idea quality level.
Economically, these are not equal.
The system must measure not only intelligence, but commitment.

8. Support Model for Partnered Projects
Support is not automatic.
The AI Flag system only identifies potential.
After that, the human team reviews the project.
If the project is considered worth supporting, the builder is contacted
and the project is evaluated in greater detail.
This includes:

project goals

technical structure

resource needs

economic potential

development timeline

applicability

If both parties agree on partnership, support begins.

Support is not fixed.

Each partnered project may receive different forms of support based on its actual needs.

Because every project differs in:

technical depth

development complexity

risk level

economic goals

Support may include:

compute power

high-context access

advanced model access

testing infrastructure

technical guidance

strategic guidance

The goal is not to support everyone.

The goal is to support valuable projects correctly.

9. Support and Partnership Offer Model

After human evaluation is completed, the platform may present an official offer to the builder.

This offer defines:

support scope

responsibilities of both parties

rights-sharing model

economic structure

The offer is mutually reviewed.

The builder is not obligated to accept.

The platform is not obligated to offer.

If accepted, the official partnership begins.

This partnership may include:

license sharing

revenue sharing

project-based partnership

strategic rights sharing

This is not forced ownership.

It is a voluntary value partnership.

10. Continuity and Protection of Shared Work

This is not a forced ownership system.

Participation is based on free will.

All rules are clearly defined before support begins.

Both parties knowingly accept them.

Once support begins, the project may evolve beyond an individual idea into a jointly developed asset.

Therefore, if the builder leaves the process, the project does not automatically end.

A builder may:

lose interest

face health issues

experience life changes

withdraw from the project

This is natural.

But the platform's effort cannot simply disappear.

Under the pre-agreed contract, the platform may protect its rights.

These rights may include:

continuing the project

taking over the project

executing license rights

protecting economic rights

The goal is not to trap the builder.

The goal is to protect shared work.

11. Platform Learning Layer

This system does not only select builders.

It also improves the platform.

The platform learns:

new problem areas

new solution models

new sector demands

new production patterns

Builders are not only recipients of support.

They are also strategic learning sources for the platform.

This creates a competitive advantage.

12. The Natural Result of Competition

If one platform adopts this model, others will be forced to respond.

The reason is simple:

Successful builders attract new builders.

This works similarly to:

scholarship systems

accelerators

venture funds

Competition will no longer be only about model quality.
Builder quality will become a competitive field.

13. A Builder Is Not a One-Time Asset

A builder is not a single project.

The real value is:

production capacity.

Today one project.

Tomorrow another.

Then another.

The system should invest not in projects,
but in builders.

Because builders are renewable assets.

14. The Exit Problem

Successful builders may:

move to local models

move to competitors

build their own infrastructure

This is natural.

However, for most builders, high-quality cloud-supported production environments are more efficient and sustainable than building independent local systems.

Therefore, retention should not come from force,
but from superior value creation.

15. Ecosystem Loop

AI discovers

→ team evaluates

→ live validation happens

→ commitment analysis happens

→ partnership offer is made

→ support begins

→ project grows

→ success emerges

→ economic sharing happens

→ new builders are supported

This closed loop creates:

a self-sustaining innovation economy.

Conclusion

Today's AI economy is a subscription economy.

Tomorrow's AI economy may become a production economy.
This model can:

discover invisible builders

reduce resource limitations

accelerate production capacity

align platforms and builders around shared value

create a new level of competition

The future question may no longer be:
Which AI is the strongest?
The real question may become:
Which AI has helped create the most successful builders?

Development Note

This model is not proposed as a fixed system.
As AI, builder behavior, and competition evolve, this system may evolve into new layers and new operational models.
Support structures, partnership models, licensing mechanisms, and builder evaluation systems may all improve over time.
This work is not a final model.
It is an expandable foundation.
The real strength of this model may not only be in its first version, but in the future layers of ideas it enables.
This is not the final word.
It is a foundation stone.
